Comprehensions Introduction

Comprehensions are a compact way to transform a set of data into another

- it applies to mostly all python's structured type, i.e., lists, sets, dictionaries
- it is in contrast to list all the elements

Some Basic comprehensions applied to lists, sets and dictionaries respectively

- a list composed of the first ten integers

>>> [elem **for** elem **in** range(1,10)] [1, 2, 3, 4, 5, 6, 7, 8, 9]

- a set composed of the first ten even integers

>>> {elem*2 **for** elem **in** range(1,10)} {2, 4, 6, 8, 10, 12, 14, 16, 18}

- a dictionary composed of the first ten couples "n, n^2 "

Playing around with ... Implementing the LS Command

```
import os, sys, time, humanize
                    from stat import *
Nalter Cazzola
                   modes = {'r': (S_IRUSR,S_IRGRP,S_IROTH), 'w': (S_IWUSR,S_IWGRP,S_IWOTH), 'x': (S_IXUSR,S_IXGRP,S_IXOTH)}
Playing around
                      s = 'd' if S_ISDIR(mode) else "-"
                      for i in range(3):
                         for j in ['r','w','x']:
                            s += j if S_IMODE(mode) & modes[j][i] else '-'
                   def format date(date):
                     d = time.localtime(date)
                      return "{0:4}-{1:02d}-{2:02d} {3:02d}:{4:02d}:{5:02d}".format(
                         d.tm_year, d.tm_mon, d.tm_mday, d.tm_hour, d.tm_min, d.tm_sec)
                      print("List of {0}:".format(os.getcwd()))
                      for file in os.listdir(dir):
                         metadata = os stat(file)
                         print("{2} {1:6} {3} {0} ".format(file, approximate_size(metadata.st_size, False), \
                            format_mode(metadata.st_mode), format_date(metadata.st_mtime)))
                   if __name__ == "__main__": ls(sys.argv[1])
```

Comprehensions To Filter out Elements of a Dataset

Comprehensions Walter Cazzola

Playing around Comprehensions definition

Multiple Values Examples Comprehensions can reduce the elements in the dataset after a constraint.

E.g., to select perfect squares out of the first 100 integers

>>> [elem for elem in range(1,100) if (int(elem**.5))**2 == elem]
[1, 4, 9, 16, 25, 36, 49, 64, 81]

- range(1,100) generates a list of the first 100 integers:
- the comprehension skims through the list selecting those elements whose square of the integral part of its square roots are equal to the element itself

E.g., to select the odd numbers out of a tuple

>>> {x for x in (1, 22, 31, 23, 10, 11, 11, -1, 34, 76, 778, 10101, 5, 44) if x = 0 {1, 5, 11, 10101, 23, -1, 31}

- note that the second Il is removed from the set;
- the set does not respect the tuple order (it is not ordered at

Slide 4 of 8

Comprehensions To Select Multiple Values

Jahter Cazzola

Slide 5 of 8

Comprehensions can select multiple values out of the dataset.

E.g., to swap keys and values in the dictionary

```
>>> a_dict = {'a': 1, 'b': 2, 'c': 3}
>>> {value:key for key, value in a_dict.items()}
{1: 'a', 2: 'b', 3: 'c'}
```

Comprehensions can select values out of multiple datasets

E.g., to merge two sets in a set of couples

```
>>> english = ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', ..., 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z']  
>>> greek = ['a', '\beta', \c', '\b', '\c', '\c'
```

E.g., to calculate the Cartesian product

>>> {(x,y) for x in range(3) for y in range(5)} $\{(0,1),(1,2),(0,0),(2,2),(1,1),(1,4),(0,2),(2,0),(1,3),(2,3),(2,1),(0,4),(2,4),(0,3),(1,0)\}$

Comprehensions Quicksort

Valter Cazzola

Examples

```
def quicksort(s):
   if len(s) == 0: return []
   else:
     return quicksort([x for x in s[1:] if x < s[0]]) + \</pre>
            [s[0]] +\
            quicksort([x for x in s[1:] if x \ge s[0])
if __name__ == "__main__":
   print(quicksort([]))
   print(quicksort([2, 4, 1, 3, 5, 8, 6, 7]))
   print(quicksort("pineapple"))
   print(''.join(quicksort('pineapple')))
```

```
[23:22]cazzola@ulik:~/esercizi-pa>python3 quicksort.py
[1, 2, 3, 4, 5, 6, 7, 8]
['a', 'e', 'e', 'i', 'l', 'n', 'p', 'p', 'p']
aeeilnppp
```

Comprehensions Prime Numbers Calculation

comprehension Natter Cazzola

Examples

Classic approach to the prime numbers calculation

```
def is_prime(x):
    div =2
    while div <= math.sqrt(x):</pre>
      if x%div == 0: return False
      else: div += 1
    return True
if __name__ == "__main__":
    primes = []
    for i in range(1, 50):
      if is_prime(i): primes.append(i)
    print(primes)
```

The algorithm again but using comprehensions

```
div = [elem for elem in range(2,int(math.sqrt(x))+1) if x%elem ==0 ]
   return len(div) == 0
if __name__ == "__main__":
   print([elem for elem in range(1, 50) if is_prime(elem)])
```

[8:50]cazzola@ulik:~/esercizi-pa>python3 imp-sieve.py [1, 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47] [1:31]cazzola@ulik:~/esercizi-pa>python3 sieve.py [1, 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47]
